Overview

Principle Component Analysis is widely used in data exploration, dimension reduction, data visualization. The aim is to transform original data into uncorrelated linear combinations of the original data while keeping the information contained in the data. High dimensional data tends to show clusters in lower dimensional view.

Clustering Analysis is another form of EDA. Here we are hoping to group data points which are close to each other within the groups and far away between different groups. Clustering using PC's can be effective. Clustering analysis can be very subjective in the way we need to summarize the properties within each group.

Both PCA and Clustering Analysis are so called unsupervised learning. There is no response variables involved in the process.

For supervised learning, we try to find out how does a set of predictors relate to some response variable of the interest. Multiple regression is still by far, one of the most popular methods. We use a linear models as a working model for its simplicity and interpretability. It is important that we use domain knowledge as much as we can to determine the form of the response as well as the function format of the factors on the other hand.

0.1 Objectives

- PCA
- SVD
- Clustering Analysis
- Linear Regression

0.2 Review materials

- Study Module 2: PCA
- Study Module 3: Clustering Analysis
- Study Module 4: Multiple regression

0.3 Data needed

- NLSY79.csv
- brca_subtype.csv
- brca_x_patient.csv

1 Case study 1: Self-seteem

Self-esteem generally describes a person's overall sense of self-worthiness and personal value. It can play significant role in one's motivation and success throughout the life. Factors that influence self-esteem can be inner thinking, health condition, age, life experiences etc. We will try to identify possible factors in our data that are related to the level of self-esteem.

In the well-cited National Longitudinal Study of Youth (NLSY79), it follows about 13,000 individuals and numerous individual-year information has been gathered through surveys. The survey data is open to public here. Among many variables we assembled a subset of variables including personal demographic variables in different years, household environment in 79, ASVAB test Scores in 81 and Self-Esteem scores in 81 and 87 respectively.

The data is store in NLSY79.csv.

Here are the description of variables:

Personal Demographic Variables

- Gender: a factor with levels "female" and "male"
- Education 05: years of education completed by 2005
- HeightFeet05, HeightInch05: height measurement. For example, a person of 5'10 will be recorded as HeightFeet05=5, HeightInch05=10.
- Weight05: weight in lbs.
- Income 87, Income 05: total annual income from wages and salary in 2005.
- Job87 (missing), Job05: job type in 1987 and 2005, including Protective Service Occupations, Food Preparation and Serving Related Occupations, Cleaning and Building Service Occupations, Entertainment Attendants and Related Workers, Funeral Related Occupations, Personal Care and Service Workers, Sales and Related Workers, Office and Administrative Support Workers, Farming, Fishing and Forestry Occupations, Construction Trade and Extraction Workers, Installation, Maintenance and Repairs Workers, Production and Operating Workers, Food Preparation Occupations, Setters, Operators and Tenders, Transportation and Material Moving Workers

Household Environment

- Imagazine: a variable taking on the value 1 if anyone in the respondent's household regularly read magazines in 1979, otherwise 0
- Inewspaper: a variable taking on the value 1 if anyone in the respondent's household regularly read newspapers in 1979, otherwise 0
- Ilibrary: a variable taking on the value 1 if anyone in the respondent's household had a library card in 1979, otherwise 0
- MotherEd: mother's years of education
- FatherEd: father's years of education
- FamilyIncome78

Variables Related to ASVAB test Scores in 1981

Test	Description
AFQT	percentile score on the AFQT intelligence test in 1981
Coding	score on the Coding Speed test in 1981
Auto	score on the Automotive and Shop test in 1981
Mechanic	score on the Mechanic test in 1981
Elec	score on the Electronics Information test in 1981
Science	score on the General Science test in 1981
Math	score on the Math test in 1981
Arith	score on the Arithmetic Reasoning test in 1981
Word	score on the Word Knowledge Test in 1981
Parag	score on the Paragraph Comprehension test in 1981
Numer	score on the Numerical Operations test in 1981

Self-Esteem test 81 and 87

We have two sets of self-esteem test, one in 1981 and the other in 1987. Each set has same 10 questions. They are labeled as Esteem81 and Esteem87 respectively followed by the question number. For example, Esteem81_1 is Esteem question 1 in 81.

The following 10 questions are answered as 1: strongly agree, 2: agree, 3: disagree, 4: strongly disagree

- Esteem 1: "I am a person of worth"
- Esteem 2: "I have a number of good qualities"
- Esteem 3: "I am inclined to feel like a failure"
- Esteem 4: "I do things as well as others"
- Esteem 5: "I do not have much to be proud of"
- Esteem 6: "I take a positive attitude towards myself and others"
- Esteem 7: "I am satisfied with myself"
- Esteem 8: "I wish I could have more respect for myself"
- Esteem 9: "I feel useless at times"
- Esteem 10: "I think I am no good at all"

1.1 Data preparation

Load the data. Do a quick EDA to get familiar with the data set. Pay attention to the unit of each variable. Are there any missing values?

1.2 Self esteem evaluation

Let concentrate on Esteem scores evaluated in 87.

- 0. First do a quick summary over all the Esteem variables. Pay attention to missing values, any peculiar numbers etc. How do you fix problems discovered if there is any? Briefly describe what you have done for the data preparation.
- 1. Reverse Esteem 1, 2, 4, 6, and 7 so that a higher score corresponds to higher self-esteem. (Hint: if we store the esteem data in data.esteem, then data.esteem[, c(1, 2, 4, 6, 7)] <- 5 data.esteem[, c(1, 2, 4, 6, 7)] to reverse the score.)
- 2. Write a brief summary with necessary plots about the 10 esteem measurements.
- 3. Do esteem scores all positively correlated? Report the pairwise correlation table and write a brief summary.
- 4. PCA on 10 esteem measurements. (centered but no scaling)
 - a) Report the PC1 and PC2 loadings. Are they unit vectors? Are they orthogonal?
 - b) Are there good interpretations for PC1 and PC2? (If loadings are all negative, take the positive loadings for the ease of interpretation)
 - c) How is the PC1 score obtained for each subject? Write down the formula.
 - d) Are PC1 scores and PC2 scores in the data uncorrelated?
 - e) Plot PVE (Proportion of Variance Explained) and summarize the plot.
 - f) Also plot CPVE (Cumulative Proportion of Variance Explained). What proportion of the variance in the data is explained by the first two principal components?
 - g) PC's provide us with a low dimensional view of the self-esteem scores. Use a biplot with the first two PC's to display the data. Give an interpretation of PC1 and PC2 from the plot. (try ggbiplot if you could, much prettier!)
- 5. Apply k-means to cluster subjects on the original esteem scores
 - a) Find a reasonable number of clusters using within sum of squared with elbow rules.
 - b) Can you summarize common features within each cluster?

- c) Can you visualize the clusters with somewhat clear boundaries? You may try different pairs of variables and different PC pairs of the esteem scores.
- 6. We now try to find out what factors are related to self-esteem? PC1 of all the Esteem scores is a good variable to summarize one's esteem scores. We take PC1 as our response variable.
 - a) Prepare possible factors/variables:
 - EDA the data set first.
 - Personal information: gender, education (05), log(income) in 87, job type in 87. Weight05 (lb) and HeightFeet05 together with Heightinch05. One way to summarize one's weight and height is via Body Mass Index which is defined as the body mass divided by the square of the body height, and is universally expressed in units of kg/m². Note, you need to create BMI first. Then may include it as one possible predictor.
 - Household environment: Imagazine, Inewspaper, Ilibrary, MotherEd, FatherEd, FamilyIncome78. Do set indicators Imagazine, Inewspaper and Ilibrary as factors.
 - You may use PC1 of ASVAB as level of intelligence
 - b) Run a few regression models between PC1 of all the esteem scores and suitable variables listed in a). Find a final best model with your own criterion.
 - How did you land this model? Run a model diagnosis to see if the linear model assumptions are reasonably met.
 - Write a summary of your findings. In particular, explain what and how the variables in the model
 affect one's self-esteem.

2 Case study 2: Breast cancer sub-type

The Cancer Genome Atlas (TCGA), a landmark cancer genomics program by National Cancer Institute (NCI), molecularly characterized over 20,000 primary cancer and matched normal samples spanning 33 cancer types. The genome data is open to public from the Genomic Data Commons Data Portal (GDC).

In this study, we focus on 4 sub-types of breast cancer (BRCA): basal-like (basal), Luminal A-like (lumA), Luminal B-like (lumB), HER2-enriched. The sub-type is based on PAM50, a clinical-grade luminal-basal classifier.

- Luminal A cancers are low-grade, tend to grow slowly and have the best prognosis.
- Luminal B cancers generally grow slightly faster than luminal A cancers and their prognosis is slightly worse.
- HER2-enriched cancers tend to grow faster than luminal cancers and can have a worse prognosis, but they are often successfully treated with targeted therapies aimed at the HER2 protein.
- Basal-like breast cancers or triple negative breast cancers do not have the three receptors that the
 other sub-types have so have fewer treatment options.

We will try to use mRNA expression data alone without the labels to classify 4 sub-types. Classification without labels or prediction without outcomes is called unsupervised learning. We will use K-means and spectrum clustering to cluster the mRNA data and see whether the sub-type can be separated through mRNA data.

We first read the data using data.table::fread() which is a faster way to read in big data than read.csv().

1. Summary and transformation

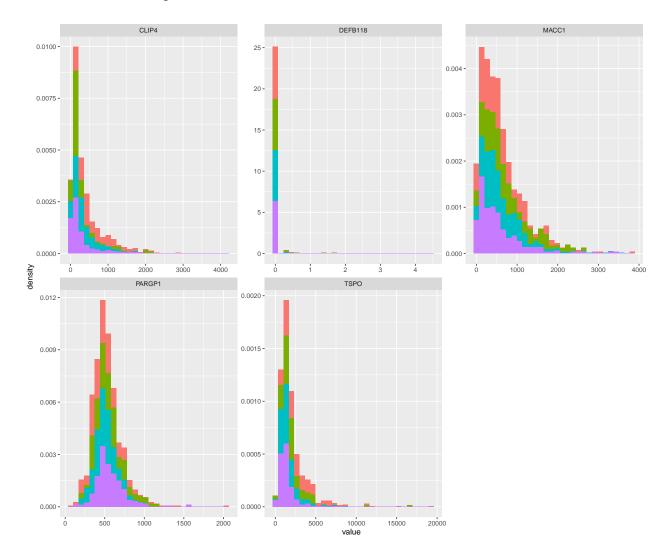

a) How many patients are there in each sub-type?

Table 2: Patients in each sub-type

Basal	Her2	LumA	LumB
208	91	628	233

b) Randomly pick 5 genes and plot the histogram by each sub-type.

'stat_bin()' using 'bins = 30'. Pick better value with 'binwidth'.

c) Remove gene with zero count and no variability. Then apply logarithmic transform.

278 genes were removed

[1] 1160 19947

[1] 1160 19669

2. Apply kmeans on the transformed dataset with 4 centers and output the discrepancy table between the real sub-type brca_subtype and the cluster labels.

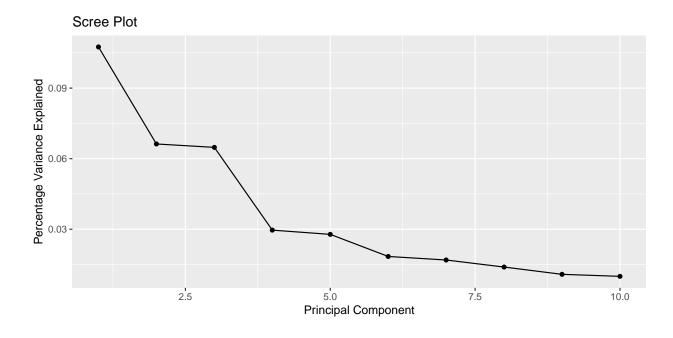

```
## user system elapsed
## 10.835 0.122 10.960
```

	1	2	3	4
Basal	1	17	3	187
Her2	39	9	26	17
LumA	392	82	154	0
LumB	98	22	111	2

- 3. Spectrum clustering: to scale or not to scale?
 - a) Apply PCA on the centered and scaled dataset. How many PCs should we use and why? You are encouraged to use irlba::irlba().

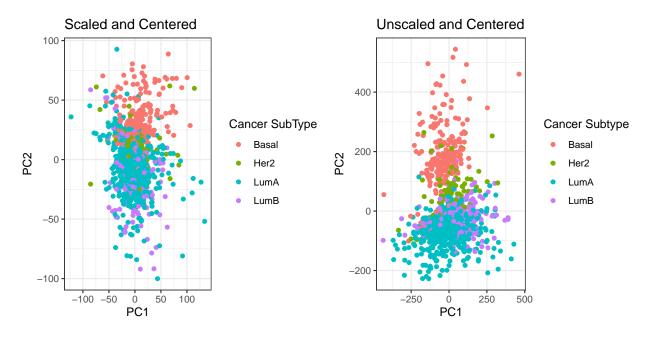

Will use 2 PCs for the centered and scaled and 4 for the centered but not scaled

Warning: 'qplot()' was deprecated in ggplot2 3.4.0.

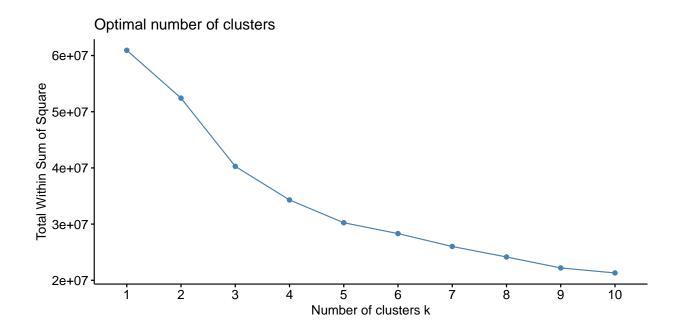

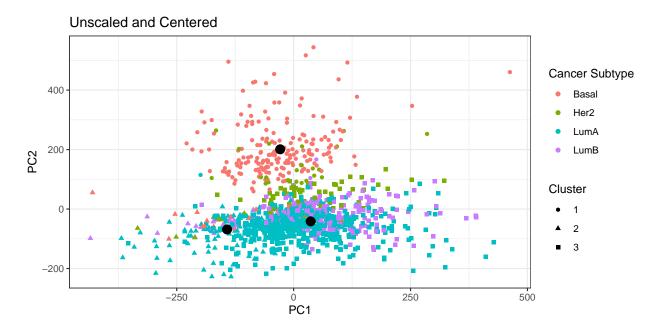

b) Plot PC1 vs PC2 of the centered and scaled data and PC1 vs PC2 of the centered but unscaled data sid

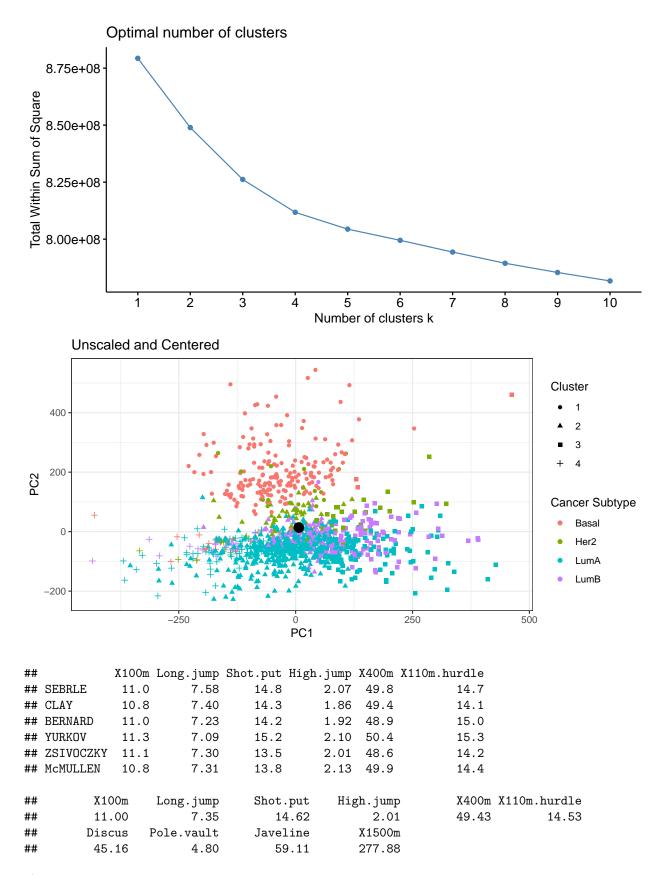

- 4. Spectrum clustering: center but do not scale the data
 - a) Use the first 4 PCs of the centered and unscaled data and apply kmeans. Find a reasonable number of clusters using within sum of squared with the elbow rule.

b) Choose an optimal cluster number and apply kmeans. Compare the real sub-type and the clustering labe

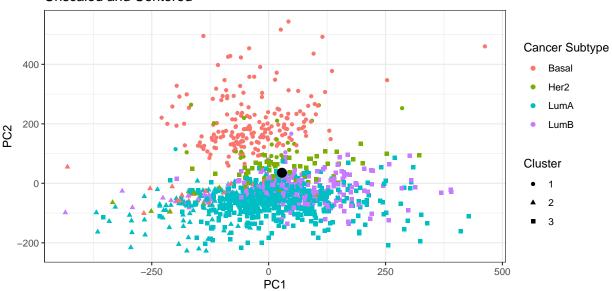

c) Compare the clustering result from applying kmeans to the original data and the clustering result fr

d) Now we have an x patient with breast cancer but with unknown sub-type. We have this patient's mRNA s

3 Case study 3: Auto data set

This question utilizes the Auto dataset from ISLR. The original dataset contains 408 observations about cars. It is similar to the CARS dataset that we use in our lectures. To get the data, first install the package ISLR. The Auto dataset should be loaded automatically. We'll use this dataset to practice the methods learn so far. Original data source is here: https://archive.ics.uci.edu/ml/datasets/auto+mpg

Get familiar with this dataset first. Tip: you can use the command <code>?ISLR::Auto</code> to view a description of the dataset.

```
## [1] "mpg" "cylinders" "displacement" "horsepower" "weight"
## [6] "acceleration" "year" "origin" "name"
```

3.1 EDA

Explore the data, with particular focus on pairwise plots and summary statistics. Briefly summarize your findings and any peculiarities in the data.

All of the variables are significant at the 0.01 level. Year is an extremely significant variable. Our

3.3 Categorical predictors

Remember that the same variable can play different roles! Take a quick look at the variable cylinders, and try to use this variable in the following analyses wisely. We all agree that a larger number of cylinders will

lower mpg. However, we can interpret cylinders as either a continuous (numeric) variable or a categorical variable.

- a) Fit a model that treats cylinders as a continuous/numeric variable. Is cylinders significant at the 0.01 level? What effect does cylinders play in this model?
- b) Fit a model that treats cylinders as a categorical/factor. Is cylinders significant at the .01 level? What is the effect of cylinders in this model? Describe the cylinders effect over mpg.
- c) What are the fundamental differences between treating cylinders as a continuous and categorical variable in your models?
- d) Can you test the null hypothesis: fit0: mpg is linear in cylinders vs. fit1: mpg relates to cylinders as a categorical variable at .01 level?

3.4 Results

Final modeling question: we want to explore the effects of each feature as best as possible. You may explore interactions, feature transformations, higher order terms, or other strategies within reason. The model(s) should be as parsimonious (simple) as possible unless the gain in accuracy is significant from your point of view.

- a) Describe the final model. Include diagnostic plots with particular focus on the model residuals and diagnoses.
- b) Summarize the effects found.
- c) Predict the mpg of the following car: A red car built in the US in 1983 that is 180 inches long, has eight cylinders, displaces 350 cu. inches, weighs 4000 pounds, and has a horsepower of 260. Also give a 95% CI for your prediction.

4 Simple Regression through simulations

4.1 Linear model through simulations

This exercise is designed to help you understand the linear model using simulations. In this exercise, we will generate (x_i, y_i) pairs so that all linear model assumptions are met.

Presume that \mathbf{x} and \mathbf{y} are linearly related with a normal error $\boldsymbol{\varepsilon}$, such that $\mathbf{y} = 1 + 1.2\mathbf{x} + \boldsymbol{\varepsilon}$. The standard deviation of the error ε_i is $\sigma = 2$.

We can create a sample input vector (n = 40) for **x** with the following code:

```
# Generates a vector of size 40 with equally spaced values between 0 and 1, inclusive x \leftarrow seq(0, 1, length = 40)
```

4.1.1 Generate data

Create a corresponding output vector for \mathbf{y} according to the equation given above. Use set.seed(1). Then, create a scatterplot with (x_i, y_i) pairs. Base R plotting is acceptable, but if you can, please attempt to use ggplot2 to create the plot. Make sure to have clear labels and sensible titles on your plots.

4.1.2 Understand the model

- i. Find the LS estimates of β_0 and β_1 , using the lm() function. What are the true values of β_0 and β_1 ? Do the estimates look to be good?
- ii. What is your RSE for this linear model fit? Is it close to $\sigma = 2$?
- iii. What is the 95% confidence interval for β_1 ? Does this confidence interval capture the true β_1 ?
- iv. Overlay the LS estimates and the true lines of the mean function onto a copy of the scatterplot you made above.

4.1.3 diagnoses

- i. Provide residual plot where fitted y-values are on the x-axis and residuals are on the y-axis.
- ii. Provide a normal QQ plot of the residuals.
- iii. Comment on how well the model assumptions are met for the sample you used.

4.2 Understand sampling distribution and confidence intervals

This part aims to help you understand the notion of sampling statistics and confidence intervals. Let's concentrate on estimating the slope only.

Generate 100 samples of size n = 40, and estimate the slope coefficient from each sample. We include some sample code below, which should guide you in setting up the simulation. Note: this code is easier to follow but suboptimal; see the appendix for a more optimal R-like way to run this simulation.

```
# Inializing variables. Note b_1, upper_ci, lower_ci are vectors
x \leftarrow seq(0, 1, length = 40)
n_sim <- 100
                           # number of simulations
                           # n sim many LS estimates of beta 1 (=1.2). Initialize to 0 for now
b1 <- 0
                           # upper bound for beta_1. Initialize to 0 for now.
upper_ci <- 0
lower ci <- 0</pre>
                         # lower bound for beta_1. Initialize to 0 for now.
t_star <- qt(0.975, 38)  # Food for thought: why 38 instead of 40? What is t_star?
# Perform the simulation
for (i in 1:n_sim){I 1
  y \leftarrow 1 + 1.2 * x + rnorm(40, sd = 2)
  lse \leftarrow lm(y \sim x)
  lse_output <- summary(lse)$coefficients</pre>
  se <- lse_output[2, 2]
  b1[i] <- lse_output[2, 1]
  upper_ci[i] <- b1[i] + t_star * se
  lower_ci[i] <- b1[i] - t_star * se</pre>
}
results <- as.data.frame(cbind(se, b1, upper_ci, lower_ci))
# remove unecessary variables from our workspace
rm(se, b1, upper_ci, lower_ci, x, n_sim, b1, t_star, lse, lse_out)
```

i. Summarize the LS estimates of β_1 (stored in results\$b1). Does the sampling distribution agree with theory?

ii.	How many of graphically.	your 9	5%	confidence	intervals	capture	the tru	e $\boldsymbol{\beta}_1$?	Display	your	confidence	intervals
